Red vs Black

This project was created to find out if the color of cattle affect how much weight they gain. I fed a red steer and a black steer for 300 days. The conditions for each steer were kept identical. They were fed the same amount and kind of feed, hay, and given clean fresh water, and other like care. The black steer was the heaviest at the beginning. However, the red steer gains more weight than the black steer between each time we weigh them. Weighing each time, and recording the weights of each animal shows, that the red steer gained more weight than the black steer. However, color does not affect weight gain. It is their genetics.
