*The Power of Suggestion*

This project was designed to determine if the results of a Rorschach test could be affected using verbal and visual stimuli. This was tested by showing a group of ten males and ten females two Rorschach tests. Taking on the most popular responses for one image and a less popular one for the other. In both instances, the stimuli was a cut out of the desired image. All the data was turned into percentages. Then the results were compared to the control. After the results were compared, it was evident that there was no change in the group where a dominant image was being influenced. The percentage difference between the experiment group and the control was between zero and five percent. With the group where the stimuli were related to a reaction that was not popular, there was a meaningful difference. There was between a ten and twenty percent increase. Considering the number of other possible reactions, this is a fair increase. These results proved that people can be very malleable. The group was only exposed to the stimulus for thirty seconds, yet it was still absorbed by the subconscious and processed. It was also shown that there was more of a reaction to the trait that was being influenced in the recessive image than that of the dominant one.
