In our 2013 science fair project, the purpose was to examine the validity of various information regarding greenhouse gases produced by human activity and their impact on troposphere temperature. The process by which we obtained the information to conclude on the validity was to search through valid electronically available resources to tell fact from hype. When researching such topics, it was our objective to use only credible resources. When finished, we concluded that the amount of carbon dioxide gas produced by human activity is far smaller to cause the type of climate change indicated by modern science models from organizations such as the International Panel on Climate Change. The information shows value to the rest of human life.
